

# 13

## COMPUTER-ASSISTED RESEARCH WRITING IN THE DISCIPLINES

*Elena Cotos*

### **Introduction**

It is arguably very important for students to acquire writing skills from kindergarten through high school. In college, students must further develop their writing in order to continue on to graduate school successfully. To obtain their graduate degree, they have to be able to write good theses, dissertations, conference papers, journal manuscripts, and other research genres. However, opportunities to develop research writing skills are often limited to traditional student-advisor discussions (Pearson & Brew, 2002). Part of the problem is that graduate students are expected to be good at such writing, because if they “can think well, they can write well” (Turner, 2012, p. 18). Education and academic literacy specialists oppose this assumption. They argue that advanced academic writing competence is too complex to be automatically acquired while learning about or doing research (Aitchison & Lee, 2006). Aspiring student-scholars need to practice and internalize a style of writing that conforms to discipline-specific conventions, which are norms of writing in particular disciplines, such as chemistry, engineering, agronomy, and psychology.

Motivated by this need, the Research Writing Tutor (RWT) was designed to assist the research writing of graduate students. RWT leverages the conventions of scientific argumentation in one of the most impactful research genres—the research article. This chapter first provides a theoretical background for research writing competence. Second, it discusses the need for technology that would facilitate the development of this competence. The description of RWT as an exemplar of such technology is then followed by a review of evaluation studies. The chapter concludes with recommendations for RWT classroom integration and with directions for further development of this tool.

### ***Research Writing Competence***

Writing is a skill that includes complex thinking processes and strategies. Additionally, writers need to know who their audience is, why the audience would read their texts, and in what contexts their texts are meant to appear. Writers should also be aware of the disciplinary practices of their audience, which are reflected in specific genre norms (Perelman, 2012). From the perspective of writing and genre theories, this general description is essential when considering research writing competence.

### ***Cognitive Writing Theory***

Graduate students are novices to research writing. Theoretically, the distinction between novice and expert writers has been articulated in terms of knowledge-telling versus knowledge-transformation (Bereiter & Scardamalia, 1987). Novice writers tell their knowledge about a topic and move from one idea to the next. Expert writers, on the other hand, transform knowledge. For them, writing is a reflection-intensive activity that involves repeated planning, translating, and revising (Dunlosky & Metcalfe, 2009; Flower & Hayes, 1980; Hacker, Keener, & Kircher, 2009). Specifically, planning is considering what ideas to include and how to present them. In theoretical terms, writers create an abstract internal representation of the text by inventing ideas and setting procedural goals. Translating is putting ideas into language, or creating the

written representation of the text. Revising includes evaluation and modification of the written text to ensure that it accurately renders the intended thoughts. Expert writers not only present elaborate content, but also make effective language choices to realize communicative goals.

Cognitive models of writing highlight revision as one of the most fundamental components of the writing process and expertise (Butterfield, Hacker, & Albertson, 1996; Hayes, 2000; Hayes & Flower, 1983). At this writing stage, expert writers compare their intended representation of the text with the actual written representation. When the two representations are in conflict, they detect and diagnose the problem. This stimulates a decision of what strategy to use to modify the text. Thus, competent revision principally depends on controlling the activation of these complex higher-order thinking processes. What characterizes novice writers is ineffective detection of problems in their writing. To develop expert-like problem-solving abilities, they need to practice revision guided by feedback that makes them think and detect ineffectively expressed meaning.

## ***Genre Theory***

Research writing involves constructing, deconstructing, and reconstructing knowledge to be shared with other scientists (Badley, 2009). It is essentially a rhetorical behavior (Jolliffe & Brier, 1988) that requires novices to use the specific conventions of scientific writing. A theoretical notion that describes conventions is the notion of genres, which are classes of texts defined by a discipline's values and communicative purposes (Berkenkotter & Huckin, 1995).

The research article genre is perhaps the most wide-spread means of scientific communication. It has become a central focus in the field of English for Academic Purposes (EAP), which has embraced Swales's (1981) approach to genre theory. Swales provided a rhetorical framework grounded in the concept of *moves*, or communicative goals. For example, the Introductions of research articles are described as having three moves: establishing a territory (Move 1), establishing a niche (Move 2), and occupying the niche (Move 3). Each of these moves is realized by *steps*, or rhetorical strategies that convey specific functional meaning. For instance, to achieve the goal of Move 2, writers may use such steps as highlighting a problem or indicating a gap. The meaning of the latter can be realized using expressions such as "not previously explored," "hindered by insufficient knowledge," "scarce evidence for," etc. In such manner, this framework establishes a systematic connection between rhetorical intent and language choices, which mirror the writer's internal and written representations of the composed text.

## **Need for Technology**

Swales's EAP genre approach has been widely adopted in academic writing instruction, increasingly using large machine-readable collections of texts, called corpora. Many researchers recommend the use of search engines to query corpora for key words in context, co-occurrence of vocabulary items, and grammatical, syntactic, and positional patterns of search words (e.g., Friginal, 2013; Lee & Swales, 2006). However, few technologies have been created for scientific writing (e.g., DicSci, TYOS, SWoRD, MAKE, Mover, We-Write Persuasively), and they do not generate feedback to support expert-like revision. Existing automated writing evaluation (AWE) systems that do generate feedback on students' texts (e.g., Criterion, MyAccess!, Writer's Workbench, Writing Power, Writing Roadmap, Folio, etc.) are designed for essays and are thus not suitable for research writing. Plus, they have been criticized for inadequately representing the cognitive and rhetorical aspects of the writing construct (Perelman, 2012).

The need for feedback technologies to enhance higher-order aspects of writing is currently addressed by large-scale projects. For example, the U.S. Department of Education's Institute of Education Sciences has funded the development of the Writing Pal program described by Crossley, Allen, and McNamara ([Chapter 12](#) in this volume), which enhances writing strategy instruction through automated strategy feedback. The National Science Foundation has funded two big projects: one to develop a socio-technical

system for teaching written argumentation (Ashley, Litman, & Schunn, 2013), and the second to develop an intelligent ecosystem for science writing instruction (Schunn, Litman, & Godley, 2014). RWT expands these efforts to research genres and their rhetorical complexity.

## RWT

RWT was designed to complement advanced academic writing instruction. It integrates rhetorical feedback with scaffolding, or instructional techniques, derived from discipline-specific corpora of published research articles to enable students to progress toward deeper understanding and autonomous use of genre conventions. The current version of RWT contains three independent yet interactive modules for learning, demonstration, and feedback. Each of the modules aims to create conditions for practice necessary for the development of research writing competence.

### ***Learning Module: “Understand Writing Goals”***

The Learning Module is designed to help teachers impart genre knowledge and to help students learn the conventions of research writing. The content of the materials included here draws from the results of a pedagogically driven study of a corpus of 900 research articles published by experts in 30 disciplines. This study yielded cross-disciplinary move/step frameworks for introduction, methods, results, and discussion/conclusion (IMRD/C) sections (Cotos, Huffman, & Link, 2015). For example, the results section contains three moves: (1) showing valid progression to findings; (2) reporting the results; and (3) establishing the meaning of results. Each move contains a series of step strategies. Move 3, for instance, may be realized by explaining specific results, suggesting reasons for what may have caused the results, reflecting on anticipated or unanticipated results, and comparing results with previous research.

The Learning Module incorporates multimodal instructional materials about the move/step conventions of each IMRD/C section. The materials define the moves, explain their purposes, provide content suggestions, specify the rhetorical functions of the steps, and supply examples from the corpus. Similar materials offer so-called *Language Focus* guidelines that highlight patterns of language use. The *Language Focus* of results, for example, describes how verbs and means of comparison are used in this section.

- Verbs: present tense is generally used to locate data in a figure or a table. Past tense is used to report specific results. Either present or past tense can be used to make strong claims about the results. Modal and tentative verbs and verb phrases are used to make less confident comments (e.g., may, might, suggest, seem, appear, tend, be possible, be likely, etc.).
- Means of comparison: adjectives are used in the comparative or superlative degrees. Verbs of variation are used to report how variables fluctuate over time (e.g., rise, fall, increase, decrease, remain constant). Verbs of correlation are used to report the relationship between two or more variables (e.g., correlate with, associate with, related to).

Additionally, this module contains short videos where an instructor first introduces a given move and explains each step of the move using representative excerpts from the corpus. Then, the instructor prompts students to determine the steps in a series of examples and demonstrates how to interpret the functional meaning and language use in those step examples. In this way, a reflective process is modeled that students could apply when revising their own writing.

### ***Demonstration Module: “Explore Published Writing”***

Numerous EAP studies show that corpus-based activities can foster enhanced awareness and writing improvement (Boulton, 2010; Henry, 2007; Tono, Satake, & Miura, 2014). Identifying similarities and differences in collections of expert writing is particularly helpful for novice second language writers

(Hyland, 2004). Moreover, systematic analysis of text structure, rhetorical composition, and characteristics of language use facilitates genre learning (Tardy, 2009) and promotes critical literacy (Hammond & Macken-Horarik, 1999).

The demonstration module is designed to create conditions for such outcomes by integrating the corpora compiled and analyzed in Cotos et al. (2015). The genre conventions are illustrated through three interrelated components: *Research Articles*, *Section Structure*, and *Move/Step Examples*. The former presents complete research articles in their original published form, modeling the end documents to be prepared by students. The *Section Structure* component contains sub-corpora of separate IMRD/C section texts annotated based on the move/step frameworks introduced in the learning module. Each annotated sentence carries a color representing a move. The colors visualize the rhetorical composition of individual texts and are the same across sections to ensure consistency in the enhancement of corpus input: blue represents Move 1; red—Move 2; green—Move 3; and gold—Move 4. The structure of multiple texts can also be displayed on the same page, making it possible for students to notice patterns in the move composition of disciplinary texts. Additionally, scrolling over a sentence brings up a gloss specifying the rhetorical step it represents (Figure 13.1).

The *Move/Step Examples* component offers a search engine, known as a concordancer in EAP. Like other concordancers, it consists of a database holding the annotated sub-corpora. By hierarchically selecting a discipline, section, move, and step from respective drop-down menus, the students can retrieve all the examples of a searched step. Figure 13.2 shows examples of the step that identifies a gap. Highlighting the part that carries the step's functional meaning makes salient various language choices: "no information is available," "have not been fully understood," "there is little information available," and "are lacking in the literature." Furthermore, the concordance examples can be expanded by a click to show the annotated source text (similar to Figure 13.1). This allows students to observe how the given step is interwoven in the discourse and what kind of content may precede or follow it.

FIGURE 13.1 Screenshot Illustrating Use of Gloss.

### Feedback Module: “Analyze My Writing”

Previous works demonstrate the pedagogical value of corpus-informed feedback provided as pre-cast concordance links (Todd, 2001), concordance-based teacher feedback embedded in students’ texts (Gaskell & Cobb, 2004), and intelligent interactive feedback (Birch-Bécaas & Cooke, 2012; Chang & Kuo, 2011; Cho & Schunn, 2007). Writing produced by students exposed to corpora was found to improve, exhibiting patterns similar to those in published articles (Bianchi & Pazzaglia, 2007; Charles, 2014; Cortes, 2011).

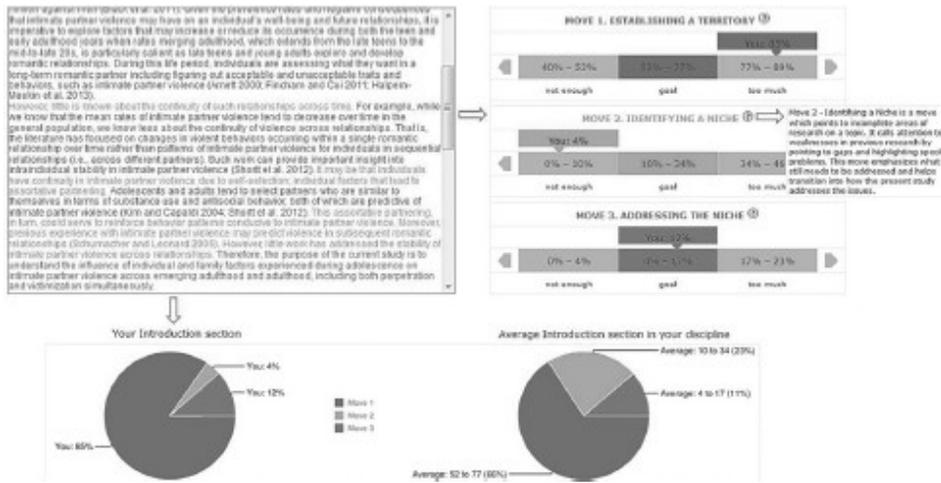

**FIGURE 13.2** Screenshot Showing Examples of Step Identifying a Gap.

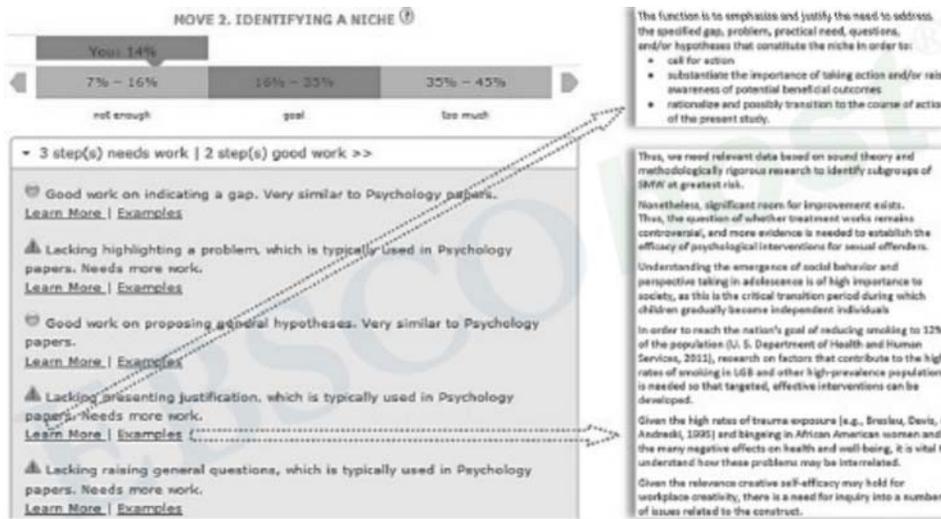

The feedback module of RWT builds on these strengths. It provides students with a platform where they can receive automated feedback on their own writing. Unlike traditional AWE systems, RWT's feedback draws students' attention to the rhetorical conventions of a research genre, as opposed to grammatical correctness and elements of style in essays. The backbone of this module is an analysis engine that is trained to classify every sentence of a student text into moves and respective steps (details in Cotos & Pendar, 2016). The results of classification are translated into different types of macro and micro-level feedback generated when students submit their drafts for automated analysis.

The macro-level feedback focuses on rhetorical composition and is visually operationalized in two ways (Figure 13.3). Specifically, the submitted draft is returned color-coded for moves. This form of feedback depicts the move structure of the draft just as the demonstration module depicts the move structure of expert texts. The second form of feedback is both visual and numerical in that it summarizes the move distribution in the draft with range bars and pie charts. Here, the draft is compared with the texts from the corpus in the student's discipline. This goal-orienting feature of the feedback (Fisher & Ford, 1998) is expected to increase motivation by allowing students to monitor their writing progress in relation to published writing. If students need a reminder of what the moves entail, they can access a brief definition by hovering over the question marks next to the moves.

The concept of functional steps is operationalized through both macro-level and micro-level feedback (Figure 13.4). Expanding the range bars for each move, RWT details whether the steps are comparable to the target discipline. It also draws the student's attention to the steps that may be lacking or may need to be improved. In support of writer's cognitive processes, this feedback is hyperlinked with the components of the learning and demonstration modules. The *Learn More* links open a new tab with instructional materials about the step that might need to be scaffolded. The *Examples* links bring the students to the concordance with step-specific excerpts from the corpus.

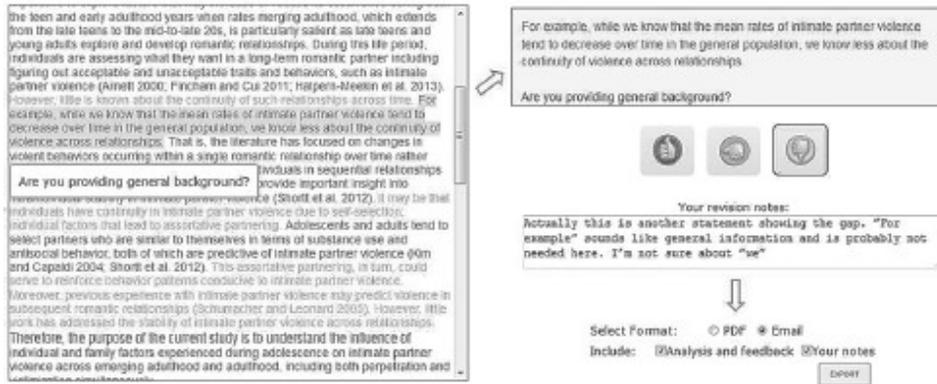

**FIGURE 13.3** Visualization of Macro-Level Feedback.

**FIGURE 13.4** Functional steps Operationalized through Macro-Level and Micro-Level Feedback.

The micro-level feedback is about the use of steps and appears as the student hovers over each sentence. Connected to the move color-coding of the draft, this type of feedback takes the form of interactive comments or clarifying questions about the rhetorical intent of a given sentence. The highlighted sentence in Figure 13.5 may not explicitly convey functional meaning, so the feedback prompts the student to think about it by asking whether this sentence intends to provide some general background to a claim (the step classified by the system as most probable for this sentence). Continuity to this instance of prompted reflection is maintained by the ‘thumbs’ and the note-taking features. In Figure 13.5, the student chose ‘thumbs down,’ indicating disagreement with the computer’s interpretation of what she meant, and made a constructive comment that she would further use for revision. All of the sentence-level feedback prompts and student notes can be exported for self-planned revision.

## Accessing and Navigating RWT

**FIGURE 13.5** Student Interaction with Micro-Level Feedback.

RWT is a web-based application in continuous development, which is why, for the time being, it is only accessible at Iowa State University in the United States. It is available to students and instructors at no cost. They need to create an account profile and log in with their institutional credentials (net-ID and password). The profile information includes the name, department, discipline, user status (e.g., doctoral/master/certificate/non-degree student, postdoctoral associate, or faculty), instructional setting (e.g., writing course, seminar, workshop) and English native/non-native speaker background. The homepage briefly introduces the tool, also linking to a short video demo, and encourages users to get started by creating a profile (Figure 13.6). The users can also contact the team for help if needed. Although access to RWT is restricted during ongoing development, guest accounts for external users can be created upon request. Ultimately, the goal is to launch this tool as open access.

**FIGURE 13.6** Creating a Profile.

RWT’s current interface is the same for all users. It is easy to navigate and is set up to engage students in greater levels of interaction. Clicking on *Understand writing goals* leads to a choice of the section the students are studying, as well as to the *Language Focus* guidelines. *Explore published writing* extends to the three components of the demonstration module, and *Analyze my writing* contains two options—to begin a new draft or continue one that is in progress. To start a new draft, students select a relevant discipline and IMRD/C section, enter the title of their paper, write or paste in the drafted content, and click on *Analyze* for feedback. When a draft for one section of their paper has been created and revised, students

can add the next section. The drafts of a given section are automatically saved and can be accessed on the same editing page. The drafts of all the sections are also archived and are accessible through the *Continue draft* button according to the title of the paper.

## Evidence of Effectiveness

Empirical evidence showing how RWT can benefit novice scholarly writers is being continuously accumulated. Research results unveil its potential to trigger reflective processes and strategies, to have a positive impact on motivation and learning gains, and to suit users with the characteristics of targeted students.

### *Enhanced Cognition*

An important intended use of RWT is to activate higher-order thinking processes during revision, which is a key stage in the development of writing expertise. The various features of the tool were found to increase students' cognitive capacity in a number of ways (Cotos, 2011). Specifically, think-aloud and screen-recording data from 16 student-participants showed that the move-level feedback provided by the prototype version of RWT helped students engage in critical reading of their drafts. Most importantly, they were able to detect a mismatch between what they meant and what they actually conveyed. Students also noticed that:

- their ideas were not always explicitly stated;
- they needed more content;
- the way they organized the content was not as logical as it seemed;
- their drafts lacked some moves or steps that were commonly used by published authors in their discipline;
- their language choices were not always appropriate for their intended meaning.

Noticing these problems was triggered by both the color-coded feedback and the numerical feedback. Two other works (Chapelle, Cotos, & Lee, 2015; Cotos, 2014) describe the cognitive reactions that were fostered by the feedback. The color-coded feedback prompted students to question what might have caused the mismatch, check whether the feedback was accurate or not, and hypothesize about what should be done to improve a problematic move. Numerical feedback facilitated setting operative goals. Because instant feedback was available for every text modification, students were able to consistently reflect and evaluate how well their ideas were translated to writing.

### *Revision Strategies*

Another study provides insight about the role of cognition in strategic text revision (Cotos, 2012). Open-ended questionnaires from 37 Masters and 68 PhD students specializing in a range of 34 disciplines showed that most students (90 percent) believed that the automated rhetorical feedback influenced their usual revision process and helped many of them (74 percent) develop new revision strategies. A random sample of 16 students was observed, interviewed, and their interaction with the tool was screen-recorded. Students' actions during revision showed that they first addressed the numerical feedback, trying to improve the move that was the farthest from the average in their discipline. At this point, the changes they made were sporadic, inconsistent, and often unsuccessful. Gradually, students' focus shifted to functional meaning. Their revision process turned into a very detailed self-verification, as they were checking the move colors against the intended steps sentence by sentence. When receiving feedback that was in disagreement with their rhetorical intent, students searched for move-specific phraseology in the annotated corpus. This appeared to be a constructive strategy often resulting in successful text modifications.

## ***Genre Learning and Writing***

The macro-level feedback and corpus-based scaffolding helped students learn and apply genre concepts. Cotos (2014) reports that 80 percent of 88 students who completed questionnaires believed that they learned the moves well, 7 percent very well, and only 13 percent a little. Responses to a qualitative survey suggest that 77 percent thought they could transfer what they learned to their actual writing. Many students (59 percent) presumed that learning occurred because the corpus-based affordances helped them acquire a better understanding of the moves and steps. Another 22 percent attributed learning to the feedback and its ability to draw their attention to the rhetorical composition of their drafts. Some students (12 percent) noted that rhetorical feedback was helpful for learning how to operate with the genre concepts. An additional factor was the practice of revision exercised through multiple resubmissions of modified text. Students explained that this practice opportunity helped them consolidate their unseasoned genre knowledge. The more they revised and resubmitted, the more problems they could detect and thus the more successful modifications they were able to make.

Students' knowledge of genre conventions before and after interacting with the tool was assessed through pre and post-tests. There was a significant difference in the pre-test scores and the post-test scores, clearly indicating learning gains. Similarly, statistical analysis comparing 210 first and final drafts demonstrated that students' writing improved significantly. It is worth mentioning that students mostly improved content, language use, and structure.

## ***Affect and Motivation***

Interaction with both the prototype and the current version of RWT was found to exert impact on students at affective and intrinsic levels. Most of the students (92 percent) in Cotos (2012) noted that they were excited to see improvement when new feedback was returned, and their desire to improve increased progressively. A third of these students shared a feeling of accomplishment. In some instances, repeated unsuccessful text modifications caused disappointment and frustration. As the revision continued, however, positive experience appeared to be more frequent compared to negative. This was in part because the students were coming to realize how important it is to be rhetorically and linguistically explicit. Corpus-based scaffolding features and comparison with published disciplinary texts also boosted their motivation.

## ***Learner Fit***

A user study investigated the appropriateness of RWT for the revision task and for graduate students in different disciplines (Cotos & Huffman, 2013). The tool was introduced to nine students in a writing course that focused on producing a publishable quality research article. Multiple types of evidence showed that all RWT's features facilitated revision. RWT also promoted the necessary degree of learner control. Students tended to interact with its features in deliberate and exploratory ways, controlling their own pace and accessing certain types of feedback when they thought it was most appropriate. All of them evaluated the different forms of feedback as helpful, because they were directly applicable to performing the writing task. The discipline-specific nature of the feedback was perceived as suitable for individual learners.

Huffman (2015) explored 11 students' first-time interaction behaviors with RWT in a similar writing course. The results of time-on-task analysis showed that, as in Cotos and Huffman (2013), the students exercised the necessary degree of learner control by selecting what feedback and scaffolding to interact with depending on what they needed at a certain point in the revision process. Some students chose to use multiple features, and others maintained interaction with fewer features in a sequenced cyclical manner. Students' most frequently interacted with their color-coded drafts and with the 'thumbs,' taking notes on how to go about modifying specific sentences. The demonstration module was accessed particularly often.

It was perceived as helpful, because the corpus-based examples illustrated how published authors compose their discourse both structurally and rhetorically. Whether opting for one or another type of interaction behavior, the students believed that RWT enabled them to self-regulate during revision.

## **Utility**

A study by Ramaswamy (2012) examined perceived usability and usefulness of RWT's feedback and demonstration modules, as well as the level of trust depending on the context of use. Three groups of graduate students were surveyed: one group consisted of 9 students enrolled in a graduate writing course; the second group of 24 students who participated in a month-long series of research writing seminars; and third group of 6 students who had never received any formal instruction in research writing. Interestingly, the less students knew about research writing, the more they tended to rely on the move feedback and trust the step feedback provided at sentence level. Students who had sufficient knowledge of genre conventions, but no teacher support, were more reflective. They liked having the computer provide rhetorical feedback, because it helped them think and self-analyze their writing. A participant even compared the feedback with the comments students receive from their major professors. Overall, the students' evaluated RWT as being user-friendly and easy to navigate, with consistently designed and well-integrated features, and visually appealing. In terms of usefulness, the different types of feedback were rated as comprehensible, stimulating deeper thinking, and motivating revision actions. Students expressed willingness to continue using this tool in the future, whether independently or as part of formal instruction.

## **Integrating the Technology for Learning**

RWT is not bound to a specific curriculum. Each of its three modules can be used to complement classroom activities in ways that are appropriate to the learning objectives, which is why RWT does not impose a pre-determined path conditioned by prerequisite steps. The materials in the learning module can be assigned by teachers as homework either before the research article conventions are introduced in class, or after that for the purpose of knowledge consolidation. In lieu of EAP corpus-based approaches, teachers can use the demonstration module to devise discovery learning tasks (see Johns, 2002), in which students explore disciplinary corpora. Their observations of how moves occur in different texts and what language is used to communicate specific shades of meaning can provide a sound foundation for class discussion and draft-planning activities. The feedback module can be best used for the purpose of self-analysis once the students produce their first draft. In this process, note-taking in response to the sentence-level feedback can become a systematic revision strategy. It is highly recommended for teachers to model self-analysis with RWT in class in order to make sure that students engage in productive reflection and are able to detect mismatches between the mental and written representations of their texts.

Although initially designed to enhance graduate writing pedagogy, RWT can be used in other learning environments and levels of instruction. For example, it has been introduced to graduate students who seek scientific writing assistance in workshops, peer writing groups, and individual consultations with writing tutors at Iowa State. In these relatively autonomous learning environments, students can determine their own needs-based ways of interaction with RWT. Generally, they begin with the feedback module and use the other two modules when needing to understand genre concepts. RWT could also be used with advanced writers in high school, particularly where the learning of sciences includes research experiences and capstone project reports. Irrespective of the context of use, the tool's most essential advantage is integrating genre and disciplinary conventions in a platform for independent writing practice.

## **Limitations and Future Directions**

RWT is a pioneering genre-based system, which draws on theoretical tenets, EAP pedagogical principles, and disciplinary corpora of research writing. Its modules facilitate the learning of scientific writing

conventions. The rhetorical feedback in the feedback module, in particular, warrants students' engagement in an interaction that stimulates necessary reflective processes and promotes revision for improvement.

Implementations of RWT in different contexts of use and the study of students' interactions with this tool have provided directions for future improvements. Undoubtedly, corpora from 30 disciplines are helpful to a rather broad representation of students. However, students whose discipline is not included in RWT may find it less suitable for their writing needs. Growing this tool to incorporate all possible disciplines is certainly a daunting and perhaps unrealistic endeavor. Nonetheless, empirical evidence obtained so far suggest that all three modules can be useful regardless of whether the discipline is present in RWT or not (if students are given an explanation of how existing features could be efficiently utilized). For example, the sentence-level feedback is helpful to anyone, because it can facilitate self-reflection that is needed to trigger cognitive activities important for the revision process. Similarly, because the linguistic choices expressing certain rhetorical intent are functional rather than disciplinary, the concordancer in the demonstration module can be used irrespective of the discipline. In other words, students in any discipline can choose expressions like "is well-established and rapidly expanding," "has led to significant interest," "has been at the forefront of much research," and "has received considerable attention" to claim centrality of their topic.

At this point, RWT falls short compared with other writing systems in that it does not have an interface for teachers, who might prefer to have access to all students' drafts and custom-tailored progress reports. Additionally, RWT has no technical ability to allow teachers to embed their own comments on various aspects of writing quality that fall outside genre conventions. To design new components for teachers, classroom-based investigations will be conducted, and teachers' input will take center stage. Embedded peer feedback is also a desirable addition, which could create a collaborative environment for groups of students who share similar writing goals and research interests. Furthermore, research is needed to understand better how RWT might be used more efficiently and to design new features that would help students frequently and strategically activate and monitor cognitive processes (similar to Roll, Alevan, McLaren, & Koedinger, 2007). The automated analysis performed by RWT's engine also anticipates a scale-up. While it yields acceptable move/step classification measures (Cotos & Pendar, 2016), feedback accuracy could be further improved. Also, the system classifies sentences only into one move and one step, but often sentences in published texts represent more than one rhetorical function. Another goal is to analyze step sequences and to generate feedback, comparing student writing with the sequencing preferences in their discipline. With its current features and new enhancements, RWT will help novices become experts in research writing.

## Acknowledgments

RWT was developed with support from the Computation Advisory Committee sponsored by the Office of the Senior Vice President and Provost at Iowa State University of Science and Technology, USA. Funding was also provided by the Graduate College, College of Engineering, and the English Department of the College of Liberal Arts and Sciences. The author gratefully acknowledges Dr. Stephen Gilbert's continued and invaluable contribution. Gratitude is extended to all colleagues who greatly assisted the research and development, as well as to all graduate students who worked on the RWT project at different stages.
